

# HW6: Still Alive

## Solution Key

*Include your full name, CS login, and the problem number(s) on each piece of paper you hand in, and please staple your pages together before handing in.*

*While collaboration is encouraged in this class, please remember not to take away notes from collaboration sessions other than your scheduled lab section.*

*In general, if you submit a complicated, messy FSM and include no explanation of how it works, it will probably not be graded.*

### Problem 1

*Convert the following NFSM to a DFSM:*

Label the states  $A$ ,  $B$ , and  $C$ , with  $A$  being the start state,  $B$  being the top-left state, and  $C$  being the bottom-left state.

## Problem 2

Write down the regular expression for the language that the following NFSM recognizes:

The following regular expression represents the NFSM:

$$0^*1[1^* + (\varepsilon + 1^*0)0^*1]$$

This can be simplified further to  $0^*1^*0^*1$ .

**Problem 3**

Let  $\Sigma = \{0, 1, 2\}$ , and let  $L$  be the language over  $\Sigma$  that contains each string  $w$  ending with some symbol that does not occur anywhere else in  $w$ . For example, 011012, 11120, 0002, 10, and 1 are all strings in  $L$ .

- Construct a nondeterministic finite-state machine that accepts  $L$ .
- Give a regular expression describing the language  $L$ .

b.  $[(0 + 1)^*2] + [(0 + 2)^*1] + [(1 + 2)^*0]$

**Problem 4**

*Describe an algorithm that constructs an NFSM  $N$  with input alphabet  $\Sigma$  from a regular expression  $r$  over  $\Sigma$  such that  $N$  recognizes a string  $w$  if any substring of  $w$  is in the language defined by  $r$ . In other words,  $N$  recognizes the language*

$$L = \{w = xyz \mid y \text{ is in the language defined by } r \text{ and } x \in \Sigma^* \text{ and } z \in \Sigma^*\}.$$

Let  $R$  be an NFSM that recognizes the language defined by  $r$ . We construct  $N$  as follows. On the start state  $q_0$  of  $R$ , add one transition from  $q_0$  to itself for each character in  $\Sigma$  in addition to any existing transitions. Then, for each  $q$  in the set of accept states  $F$  of  $R$ , add a transition from  $q$  to itself for each character in  $\Sigma$ , in addition to any existing transitions.

This works because if  $w = xyz \in L$ , then  $N$  will loop on itself at  $q_0$  for each character in  $x$ , then compute normally for  $y$ , getting to an accept state, and then loop on that accept state for  $z$ . This means it will end on an accept state, so  $N$  will accept  $w$ .

If  $N$  accepts  $w$ , then we can split  $w$  into  $xyz$  where  $x$  is the largest prefix of  $w$  such that  $N$  ends at  $q_0$  on input  $x$ . So,  $N$  can simply loop on  $q_0$  for all of  $x$  and get the same result. Then  $y$  is the shortest string such that  $xy$  is a prefix of  $w$  and  $N$  accepts  $y$ . We know such a string exists because  $N$  accepts  $w$  and it is in its starting state after computing  $x$ , so it must get to an accepting state after that, so  $y$  must exist (even if it is empty). Then  $z$  is the rest of the  $w$ . Since  $N$  accepts  $y$ , we know that  $y$  is in the language defined by  $r$ , so  $xyz = w \in L$ .

Hence we see that  $N$  recognizes  $L$ .
